

Goal:

- **To be able to decide what outfit to wear on that day in less than 5 minutes.** The outfit must have a low level of tactile disturbance, is suitable for the weather, is not a repeat of what was worn on that week, and is available (not in the laundry)
- **User must be able to rate each of the pieces of clothing in terms of tactile comfort, and update the software on whether it is available to use.**
- Additional info impacting the energy required to make the outfit come to fruition should be considered. E.g. has it been ironed? Will wearing a super comfy outfit compromise the fairness distribution of the comfort level of other outfits throughout the week (e.g. does wearing OP level comfort outfits that are also aestheticmaxxing (I genuinely dont know how else to describe this lol) for the first 3 days of the weekday mean the last 2 would be disastrous outfits?) → maybe have a threshold of OP level outfits so it never reaches....
- **Every time an outfit is confirmed for that day, there should be a counter that keeps track of the frequency of wearing it.** A decision factor is to prioritize outfits that have low frequency of wear.
- UI shouldnt be over the top. Just a plain white background would do.
- Question:
 - should user rate pieces of clothing or the combination of clothes or both?
 - → each clothing piece should have its own ID for frequency count, and each should have its own tactile comfort rating, but there should also be a variable considering the aestheticmaxxing of the outfit as a whole.
- User should be able to upload a picture of their clothes (with transparent background) and immediately get asked what pairings go well with that piece of clothing (this should be able to be updated). Database stores those pairings along with a preference score.

Prototypes:
